Büchi's Logical Characterisation of Regular Languages

Deepak D'Souza

Department of Computer Science and Automation Indian Institute of Science, Bangalore.

12 September 2011

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Outline

Background

 Büchi's motivation: Decision procedure for deciding truth of first-order logic statements about natural numbers and their ordering. Eg.

$$\forall x \exists y (x < y).$$

- Used finite-state automata to give decision procedure.
- By-product: a logical characterisation of regular languages.

Theorem (Büchi 1960)

L is regular iff L can be described in Monadic-Second Order Logic.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

First-Order logic of $(\mathbb{N}, <)$.

- Interpreted over $\mathbb{N} = \{0, 1, 2, 3, \ldots\}.$
- What you can say:

$$x < y$$
, $\exists x \varphi$, $\forall x \varphi$, \neg , \land , \lor .

- Examples:

First-Order logic of $(\mathbb{N}, <)$.

- Interpreted over $\mathbb{N} = \{0, 1, 2, 3, \ldots\}.$
- What you can say:

$$x < y$$
, $\exists x \varphi$, $\forall x \varphi$, \neg , \land , \lor .

- Examples:

 Question: Is there an algorithm to decide if a given FO(ℕ, <) sentence is true or not?

Monadic Second-Order logic over alphabet A: MSO(A)

• Interpreted over a string $w \in A^*$.

 $w = a \ a \ b \ a \ b \ a \ b \ a \ b \\ 0 \ 1 \ 2 \ 3 \ 4 \ 5 \ 6 \ 7 \ 8$

- Domain is set of positions in w: $\{0, 1, 2, \dots, |w| 1\}$.
- "<" is interpretated as usual < over numbers.
- What we can say in the logic:
 - $Q_a(x)$: "Position x is labelled a".
 - *x* < *y*: "Position *x* is strictly less than position *y*".
 - $\exists x \varphi$: "There exists a position $x \dots$ "
 - $\forall x \varphi$: "For all positions x ..."
 - $\exists X \varphi$: "There exists a set of positions X ..."
 - $\forall X \varphi$: "For all sets of positions X ..."
 - $x \in X$: "Position x belongs to the set of positions X".

Example $MSO(\{a, b\})$ formulas

What language do the sentences below define?

$$\exists x(\neg \exists y(y < x) \land Q_a(x)).$$

$$\exists y(\neg \exists x(y < x) \land Q_b(y)).$$

 $\exists x \exists y \exists z (succ(x, y) \land succ(y, z) \land last(z) \land (Q_b(x)).$

Give sentences that describe the following languages:

- Every a is immediately followed by a b.
- Ostrings of odd length.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

MSO sentence for strings of odd length

Language $L \subseteq \{a, b\}^*$ of strings of odd length.

	а	а	Ь	а	Ь	а	Ь	а	Ь
Xe	1	0	1	0	1	0	1	0	1
Xo	0	1	0	1	0	1	0	1	0

$$\exists X_e \exists X_o (\exists x (x \in X_e) \land (\forall x ((x \in X_e) \implies \neg x \in X_o) \land (x \in X_o \implies \neg x \in X_e) \land (x \in X_e \lor x \in X_o) \land (zero(x) \implies x \in X_e) \land (\forall y((x \in X_e \land succ(x, y)) \implies y \in X_o)) \land (\forall y((x \in X_o \land succ(x, y)) \implies y \in X_e)) \land (last(x) \implies x \in X_e))).$$

First-Order Logic

- A First-Order Logic usually has a signature comprising the constants, and function/relation symbols. Eg. (0, <, +).
- Terms are expressions built out of the constants and variables and function symbols. Eg. 0, x + y, (x + y) + 0. They are interpreted as elements of the domain of interpretation.
- Atomic formulas are obtained using the relation symbols on terms of the logic. Eg. x < y, x = 0 + y, x + y < 0.
- Formulas are obtained from atomic formulas using boolean operators, and existential quantification (∃x) and universal quantification (∀x). Eg. ¬(x < y), (x < 0) ∧ (x = y), ∃x(∀y(x < y) ∧ (z < x)).
- Given a "structure" (i.e. a domain, a concrete interpretation for each constant and function/relation symbol) and an assignment for variables to values in the domain) to interpret the formulas in, each formula is either true or false.
- A formula is called a sentence if it has no=free=(unquantified)

Second-Order Logic

- In Second-Order logic, one allows quantification over relations over the domain (not just elements of the domain). Eg. ∃R(R(x,y) ⇒ x < y).
- In Monadic second-order logic, one allows quantification over monadic relations (i.e. relations of arity one, or subsets of the domain). Eg. ∃X(x ∈ X ⇒ 0 < x).

Formal Semantics of MSO

 An interpretation for the logic will be a pair (w, I) where w ∈ A* and I is an assignment of individual variables to a position in w, and set variables to a set of positions of w.

$$\mathbb{I}: Var \to pos(w) \cup 2^{pos(w)}.$$

- $\mathbb{I}[i/x]$ denotes the assignment which maps x to i and agrees with \mathbb{I} on all other individual and set variables.
- Similarly for $\mathbb{I}[S/X]$.

Formal Semantics of MSO

The satisfaction relation $w, \mathbb{I} \models \varphi$ is given by:

$$\begin{array}{lll} w, \mathbb{I} \models Q_{a}(x) & \text{iff} & w(\mathbb{I}(x)) = a \\ w, \mathbb{I} \models x < y & \text{iff} & \mathbb{I}(x) < \mathbb{I}(y) \\ w, \mathbb{I} \models x \in X & \text{iff} & \mathbb{I}(x) \in \mathbb{I}(X) \\ w, \mathbb{I} \models \neg \varphi & \text{iff} & w, \mathbb{I} \models \varphi \\ w, \mathbb{I} \models \varphi \lor \varphi' & \text{iff} & w, \mathbb{I} \models \varphi \text{ or } w, \mathbb{I} \models \varphi' \\ w, \mathbb{I} \models \exists x \varphi & \text{iff} & \text{exists } i \in pos(w) \text{ s.t. } w, \mathbb{I}[i/x] \models \varphi \\ w, \mathbb{I} \models \exists X \varphi & \text{iff} & \text{exists } S \subseteq pos(w) \text{s.t. } w, \mathbb{I}[S/X] \models \varphi \end{array}$$

Languages definable by MSO

• We say $L \subseteq A^*$ is definable in MSO(A) if there is a sentence φ in MSO(A) such that $L(\varphi) = L$.

Theorem (Büchi 1960)

 $L \subseteq A^*$ is regular iff L is definable in MSO(A).

From automata to MSO sentence

- Let $L \subseteq A^*$ be regular. Let $\mathcal{A} = (Q, s, \delta, F)$ be a DFA for L.
- To show L is definable in MSO(A).
- Idea: Construct a sentence φ_A describing an accepting run of A on a given word.
 That is: φ_A is true over a given word w precisely when A has an accepting run on w.

Let
$$Q = \{q_1, \dots, q_n\}$$
, with $q_1 = s$.
Define φ_A as
 $\exists X_1 \dots \exists X_n (\forall x) ((\bigwedge_{i \neq j} (x \in X_i) \implies \neg x \in X_j) \land \bigvee_i x \in X_i) \land (zero(x) \implies x \in X_1) \land (\bigwedge_{a \in A, i, j \in \{1, \dots, n\}, \delta(q_i, a) = q_j} ((x \in X_i \land Q_a(x) \land \neg last(x)) \implies \exists y(succ(x, y) \land y \in X_j))) \land (last(x) \implies \bigvee_{a \in A, \delta(q_i, a) \in F} (Q_a(x) \land x \in X_i))).$

Example

Consider language $L \subseteq \{a, b\}^*$ of strings of even length.

From MSO sentence to automaton

- Idea: Inductively describe the language of extended models of a given MSO formula φ by an automaton \mathcal{A}_{φ} .
- Extended models wrt set of first-order and second-order variables T = {x₁,..., x_m, X₁,..., X_n}: (w, I)
- Can be represented as a word over $A \times \{0,1\}^{m+n}$.

• For example above extended word satisfies the formula $Q_a(x_1) \land (x_2 \in X_1).$

Inductive construction of $\mathcal{A}_{\omega}^{\mathcal{T}}$.

- If φ is a formula whose free variables are in T, then we have the notion of whether w' ⊨ φ based on whether the (w, I) encoded by w' satisfies φ or not.
- Let the set of valid extended words wrt T be valid^T(A).
- We can define an automaton $\mathcal{A}_{val}^{\mathcal{T}}$ which accepts this set.
- Claim: with every formula φ in MSO(A), and any finite set of variables T containing at least the free variables of φ, we can construct an automaton A^T_φ which accepts the language L^T(φ).
- Proof: by induction on structure of φ .

$$Q_a(x), \ x < y, \ x \in Y, \ \neg \varphi, \ \varphi \lor \psi, \ \exists x \varphi, \ \exists X \varphi.$$

Back to First-Order logic of $(\mathbb{N}, <)$.

- Interpreted over $\mathbb{N} = \{0, 1, 2, 3, \ldots\}.$
- What you can say:

$$x < y$$
, $\exists x \varphi$, $\forall x \varphi$, \neg , \land , \lor .

• Examples:

 Question: Is there an algorithm to decide if a given FO(ℕ, <) sentence is true or not?

Büchi's decision procedure for $MSO(\mathbb{N}, <)$

- Büchi considered finite automata over infinite strings (so called ω-automata).
- An infinite word is accepted if there is a run of the automaton on it that visits a final state inifinitely often.
- Büchi showed that ω-automata have similar properties to classical automata: are closed under boolean operations, projection, and can be effectively checked for emptiness.
- $\bullet~{\rm MSO}$ characterisation works similarly for $\omega{\rm -automata}$ as well.
- Given a sentence φ in MSO(N, <) we can now view it as an MSO({a}) sentence.
- Construct an ω-automaton A_φ that accepts precisely the words that satisfy φ.
- Check if $L(\mathcal{A}_{\varphi})$ is non-empty.
- If non-empty say "Yes, φ is true", else say "No, it is not true."

• We saw another characterisation of the class of regular languages, this time via logic:

Theorem (Büchi 1960)

 $L \subseteq A^*$ is regular iff L is definable in MSO(A).

• We saw an application of automata theory to solve a decision procedure in logic:

Theorem (Büchi 1960)

The Monadic Second-Order (MSO) logic of $(\mathbb{N}, <)$ is decidable.
