Finite Model Theory

Lecture 4: Locality, 1-0, Fixpoints

11 November, 2015

*Foundations of Ontologies and Databases
for Information Systems
CS5130 (Winter 2015)*

Recap of Lecture 3

- ▶ Finite Model Theory approach
 - ▶ consider DBs as finite structures
 - ▶ FOL as query language
- ▶ FOL works because
 - ▶ Though FOL model checking in PSPACE w.r.t. combine complexity
 - ▶ it is in AC^0 for data complexity

Ad Exercise 3.1

- ▶ DBs may have NULL values (but structures are not incomplete)
- ▶ Domain of structure not explicitly specified
 - ▶ Natural vs. active domain semantics
 - ▶ Safety considerations needed for FOL (not the case for relational calculus/SQL)
- ▶ One can show: FOL under active domain semantics the same as SQL
- ▶ Nonetheless: It means dependency on domain.

Inexpressivity Tools

- ▶ Games as basic tool for proving inexpressivity
- ▶ Reduction again
- ▶ Still to discuss: locality
- ▶ Still to discuss: 0-1 laws

Reduce $\text{EVEN}(\prec)$ to Graph Connectivity

linear order is odd

iff

graph connected

linear order is even

iff

graph is disconnected

- ▶ Construction of graph from linear order expressible as an FOL query $Q_{red} : \text{LinOrd} \rightarrow \text{GRAPH}$

Graphics from [Libkin 09]

Reduce $\text{EVEN}(\prec)$ to Graph Connectivity

linear order is odd

iff

graph connected

linear order is even

iff

graph is disconnected

- Construction of graph from linear order expressible as an FOL query $Q_{red} : \text{LinOrd} \rightarrow \text{GRAPH}$

Graphics from [Libkin 09]

For those who do not believe (Exercise 3.3)

- ▶ Helper formulae

- ▶ $\text{succ}(x, y) : x < y \wedge \neg \exists z. x < z \wedge z < y$

- ▶ $\text{last}(x) : \neg \exists z. x < z$

- ▶ $\text{first}(x) : \neg \exists z. z < x$

- ▶ Define $Q_{\text{red}} : \text{LinOrd} \rightarrow \text{GRAPH}$ as

$$\text{red}(x, y) : (\exists z. \text{succ}(x, z) \wedge \text{succ}(z, y)) \vee$$

$$(\text{last}(y) \wedge \exists z. \text{first}(z) \wedge \text{succ}(z, x)) \vee$$

$$(\exists z. \text{last}(z) \wedge \text{succ}(y, z) \wedge \exists w. \text{first}(w) \wedge \text{succ}(w, x))$$

- ▶ Assume that CONN is expressible as FOL query ϕ_{conn} over signature $\{E\}$ for graphs.

- ▶ Then $\text{EVEN}(<)$ would be FOL expressible: $\phi_{\text{conn}}[E/\text{red}]$

ACYCL and TC are not FOL expressible

- ▶ ACYCL: Reduction EVEN \Rightarrow ACYCL as above but with one back edge from last node to first node
- ▶ Reduction for TC: CONN \Rightarrow TC
 - ▶ Add edge $E(x, y)$ for every edge $E(y, x)$
 - ▶ Compute TC on resulting graph
 - ▶ Test whether graph is complete

End of Recap

Locality

Proving Inexpressibility by Locality

- ▶ FOL has a fundamental property: locality
- ▶ Consider a binary query $Q : STRUCT(\sigma) \longrightarrow STRUC(ans)$
 - ▶ Need a formula ϕ_Q in two open variables x, y
 - ▶ The way how to describe constraints between x and y is restricted by the number of atoms and elements occurring in ϕ_Q .
- ▶ Different (comparable) locality notions
 - ▶ Bounded number of degrees property (BNDP)
 - ▶ Gaifman locality
 - ▶ Hanf locality

Proving Inexpressibility by Locality

- ▶ FOL has a fundamental property: locality
- ▶ Consider a binary query $Q : STRUCT(\sigma) \longrightarrow STRUC(ans)$
 - ▶ Need a formula ϕ_Q in two open variables x, y
 - ▶ The way how to describe constraints between x and y is restricted by the number of atoms and elements occurring in ϕ_Q .
- ▶ Different (comparable) locality notions
 - ▶ Bounded number of degrees property (BNDP)
 - ▶ Gaifman locality
 - ▶ Hanf locality

BNDP

- ▶ $in(\mathcal{G})$ = set of in-degrees of nodes in \mathcal{G}
- ▶ $out(\mathcal{G})$ = set of out-degrees of nodes in \mathcal{G}
- ▶ $degs(\mathcal{G}) = in(\mathcal{G}) \cup out(\mathcal{G})$

Definition

Q has BNDP iff there is $f_Q : \mathbb{N} \rightarrow \mathbb{N}$ s.t. for all graphs \mathcal{G} :

If there is $k \in \mathbb{N}$ s.t. $\max(degs(\mathcal{G})) \leq k$,
then $|degs(Q(\mathcal{G}))| \leq f_Q(k)$.

- ▶ Intuitively: Q disallowed to arbitrarily increase degrees of nodes

Theorem

Every FOL query has the BNDP.

Example: TC on Successor Relation Graph

- ▶ $\mathcal{G} = (\{a_0, \dots, a_n\}, \{E(a_0, a_1), \dots, E(a_{n-1}, a_n)\})$
- ▶ $in(\mathcal{G}) = out(\mathcal{G}) = \{0, 1\}$
- ▶ $in(TC(\mathcal{G})) = out(TC(\mathcal{G})) = \{0, \dots, n-1\}$

Gaifman locality

Gaifman locality defined here on graphs $\mathfrak{G} = (A, E)$
(can be generalized to arbitrary structures)

Gaifman Locality Intuitively

An m -ary query Q is **Gaifman local** iff there is a threshold (radius) r such that for all graphs:

Q cannot distinguish between tuples if their r -neighbourhoods in the graph are the same.

Theorem

Every FOL-definable query is Gaifman local.

Gaifman locality

- ▶ $\bar{a} \in A^n$ (vector of elements)
- ▶ $B_r^{\mathfrak{G}}(\bar{a}) = \{b \in A \mid d(\bar{a}, b) \leq r\}$ (radius r ball around \bar{a})
 $d(\bar{a}, b) =$ minimal path distance from $\{a_1, \dots, a_n\}$ to b
- ▶ $N_r^{\mathfrak{G}}(\bar{a})$ (r -neighbourhood of \bar{a})
subgraph induced by $B_r^{\mathfrak{G}}(\bar{a})$ in the structure (A, E, \bar{a})

Definition

An m -ary query Q (with $m > 0$) is **Gaifman-local** iff:

There exists a radius r s.t. for all \mathfrak{G} : If $N_r^{\mathfrak{G}}(\bar{a}) \simeq N_r^{\mathfrak{G}}(\bar{b})$, then $\bar{a} \in Q(\mathfrak{G})$ exactly when $\bar{b} \in Q(\mathfrak{G})$.

Example: TC is not Gaifman local

Proof

- ▶ Suppose TC is FOL definable with query Q
- ▶ Then Q is Gaifman local with some radius r
- ▶ $N_r^{\mathfrak{G}}((a, b)) \simeq N_r^{\mathfrak{G}}((b, a))$
because both subgraphs are disjoint unions of two $2r$ -chains
- ▶ But $(a, b) \in TC(\mathfrak{G})$ and $(b, a) \notin TC(\mathfrak{G})$,

Graphics from [Libkin 09]

Hanf locality

- ▶ $\mathfrak{G} = (A, E), \mathfrak{G}' = (A', E')$
- ▶ $\mathfrak{G} \rightleftarrows_r \mathfrak{G}'$ iff
there exists bijection $f : A \rightarrow A'$ s.t. for all $a \in A$:
 $N_r^{\mathfrak{G}}(a) \simeq N_r^{\mathfrak{G}'}(f(a))$
- ▶ Intuitively: $\mathfrak{G}, \mathfrak{G}'$ are pointwise similar w.r.t. to r -neighbourhoods

Definition

A Boolean query Q is **Hanf-local** iff a radius r exists s.t. for any graphs $\mathfrak{G}, \mathfrak{G}'$ with $\mathfrak{G} \rightleftarrows_r \mathfrak{G}'$ one has $Q(\mathfrak{G}) = Q(\mathfrak{G}')$.

Theorem

Every FOL definable Boolean query is Hanf-local.

Example: CONN is not Hanf-local

\mathcal{G} : two cycles of length m

\mathcal{G}' : one cycle of length $2m$

Proof

- ▶ For contradiction assume CONN is Hanf-local with parameter r
- ▶ Choose $m > 2r + 1$; f an arbitrary bijection of \mathcal{G} and \mathcal{G}'
- ▶ r -neighbourhood of any a the same: $2r$ -chain with a in the middle
- ▶ Hence $\mathcal{G} \rightleftharpoons_r \mathcal{G}'$, but: \mathcal{G}' is connected and \mathcal{G} is not.

Comparison of Locality Notions

Theorem

Hanf local \models *Gaifmann local* \models *BNDP*

Optional Slide: Adding Order

- ▶ Many applications have finite models with a linear order $<$
- ▶ Locality conditions in its original form not applicable: 1-radius already whole structure
- ▶ Consider invariant queries

Definition

A query Q over ordered structures is invariant iff for all structures \mathfrak{A} , all tuples \bar{b} and all linear orders $<_1, <_2$ on \mathfrak{A} : $\bar{b} \in Q((\mathfrak{A}, <_1))$ iff $\bar{b} \in Q((\mathfrak{A}, <_2))$

For an invariant Q define Q_{inv} on arbitrary structures as:
 $Q_{inv}(\mathfrak{A}) = Q((\mathfrak{A}, <))$ for arbitrarily chosen $<$.

Theorem

Every invariant FOL query is Gaifman-local (and so has BNDP).

0-1 law

0-1 law

An inexpressibility tool based on a probabilistic property of FOL queries

0-1-law informally

Either almost all finite structures fulfill the property or almost all do not

Example

- ▶ Boolean query $Q_1 = \forall x, y E(x, y)$ on graphs
Almost all graphs do not satisfy Q_1 (only the complete ones)
- ▶ Boolean query $Q_2 = \forall x \forall y \exists z E(z, x) \wedge \neg E(z, y)$
Almost all graphs satisfy Q_2

Formal definition 0-1 laws

- ▶ Here it is important that signature σ is relational!!
- ▶ $STRUC(\sigma, n)$: structures with domain $[n] := \{0, 1, \dots, n - 1\}$ over σ .
- ▶ For a Boolean query Q let

$$\mu_n = \frac{|\{\mathfrak{A} \in STRUC(\sigma, n) \mid Q(\mathfrak{A}) = true\}|}{|STRUC(\sigma, n)|}$$

- ▶ $\mu_n(Q)$ is the probability that a randomly chosen structure on $[n]$ satisfies Q
- ▶ $\mu(Q) = \lim_{n \rightarrow \infty} \mu_n(Q)$

Definition

A logic has 0-1-law if for every Boolean query Q expressible in it either $\mu(Q) = 0$ or $\mu(Q) = 1$.

Inexpressibility with 0-1 laws

Theorem

FOL has the 0-1- law.

- ▶ Helpful for proving inexpressibility of counting properties

Example (EVEN is not expressible in FOL)

$\mu(\text{EVEN})$ not defined because $\mu_n(\text{EVEN})$ alternates between 0 and 1.

Beyond FOL

Counting, Aggregation

- ▶ Practical languages s.a. SQL allow counting and aggregation.

Example (Departments with Average Salary > 100,000)

```
SELECT S1.Dept, AVG(S2.Salary)
FROM S1, S2
WHERE S1.Empl = S2.Empl
GROUP BY S1.Dept
HAVING SUM(S2.Salary) > 1000
```

Schema: S1(Empl, Dept), S2(Empl,Salary)

- ▶ Consider corresponding extensions of FOL
- ▶ Some of the tools shown so far still work (when non-ordered structures are considered)

FOL with counting quantifiers

Definition (FOL-AllCnt)

FOL-AllCnt is the extension of FOL with counting quantifiers and counting terms:

- ▶ $\exists^{\geq i} x. \phi(x)$: There are at least i elements x fulfilling ϕ .
- ▶ $\#\bar{x}. \phi(\bar{x})$: the number of \bar{x} fulfilling $\phi(\bar{x})$.
- ▶ Semantics defined w.r.t. 2-sorted FOL structures $\mathfrak{A} = (A, \mathbb{N}, (R^{\mathfrak{A}})_{R \in \sigma}, Arith)$
- ▶ Second domain (sort) \mathbb{N} is infinite!
- ▶ *Arith* contains (interpreted) arithmetic predicates and functions

Example

Parity of a unary predicate symbol U can be expressed by the following formula using counting quantifiers:

$$\exists j \exists i ((i + i = j) \wedge \exists^{\geq j} x U(x) \wedge \forall k (\exists^{\geq k} x U(x) \rightarrow k \leq j))$$

“There is an even number (j) of U s and there are no more than j U s”

Theorem

FOL+AllCtn queries are Hanf local (and thus Gaifman local and have the BNDP).

Aggregation

- ▶ \mathcal{F} = aggregate function = family of functions f_1, f_2, \dots with
- ▶ f_n maps n-element multisets from \mathbb{Q} to elements from \mathbb{Q} .
Example: $SUM = \{s_1, s_2, \dots, \}$ with
 $s_k(\{d_1, \dots, d_k\}) = \sum_{i=1}^k d_i$
- ▶ Allow relations and terms with 2 sorts, the additional sort being \mathbb{Q}

Definition (FOL-Aggr)

FOL-Aggr as FOL+AllCnt aggregate terms (and \mathbb{Q} instead of \mathbb{N}).

- ▶ Syntax: Terms $t(\bar{x})$ of the form $Aggr_{\mathcal{F}} \bar{y}.(\phi(\bar{x}, \bar{y}), t'(\bar{x}, \bar{y}))$
- ▶ Semantics over \mathfrak{A} for tuple \bar{b}
 - ▶ $B := \{\bar{c} \mid \mathfrak{A} \models \phi(\bar{b}, \bar{c})\}$
 - ▶ $t^{\mathfrak{A}}(\bar{b}) = f_{|B|}(\{t'^{\mathfrak{A}}(\bar{b}, \bar{c}) \mid \bar{c} \in B\})$

Locality for FOL+Aggr

Theorem

FOL-Aggr queries are Hanf-local (and thus Gaifmann-local and have the BNDP).

- ▶ If order is added, then locality is lost

Higher-Order Logics

- ▶ Second order logic (SO): Allow quantification over relations
- ▶ Vocabulary: FOL vocabulary + predicate variables X, Y, \dots
- ▶ Syntax: FOL syntax +
 - ▶ $Xt_1 \dots t_n$ is a formulae (for n -ary X and terms t_i)
 - ▶ If ϕ is a formula, then so are $\exists X\phi, \forall X\phi$
- ▶ Higher-order quantification adds expressivity
- ▶ $EVEN(\sigma)$ (for any signature σ) expressible. (Exercise)

Fixpoint Logics (FPLs)

- ▶ Reachability queries call for extension of FOL with “iteration” mechanism
- ▶ FPLs use a well-behaved self-referential process/bootstrapping
- ▶ Fixpoints as limits of this process
- ▶ Different fixpoints may exist
- ▶ Different fixpoint logics exist (e.g. largest, least)
- ▶ Most prominent in DB theory: Datalog

Example: Compute the Transitive Closure

- ▶ $E(x, y) =:$ edge of graph \mathfrak{G} ,
- ▶ $R(x, y) =:$ transitively closed relation between vertices

$$\forall x, \forall y \quad R(x, y) \leftrightarrow E(x, y) \vee (\exists z. E(x, z) \wedge R(z, y))$$

- ▶ For all graphs \mathfrak{G} find extension $\mathfrak{G}' = (\mathfrak{G}, R^{\mathfrak{G}'})$ s.t. lhs and rhs evaluate to the same relation. (*)
- ▶ Read equivalence as a iteratively applied rule from right to left

$$\boxed{X_{new}}(x, y) \leftarrow \underbrace{E(x, y) \vee (\exists z. E(x, z) \wedge X_{old}(z, y))}_{\phi(x, y, X_{old})}$$

- ▶ Induces a step(-jump)-operator F on the semantical side
- ▶ For $X \subseteq G \times G$:

$$F : X \mapsto \boxed{\{(d_1, d_2) \mid (\mathfrak{G}, X, x/d_1, y/d_2) \models \phi(x, y, X)\}}$$

- ▶ Condition (*) reread: find fixpoint R s.t. $F(R) = R$

Constructing Least fixpoints

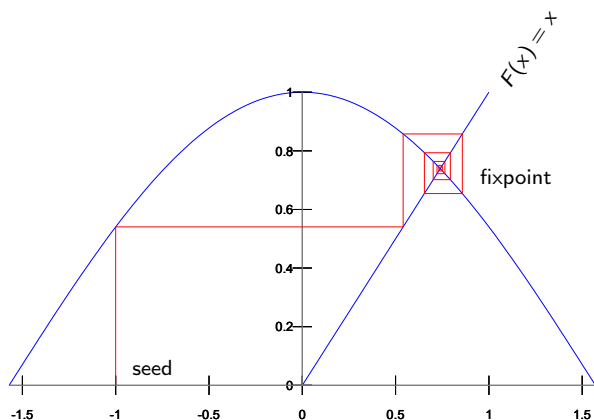

- ▶ Start with extension \emptyset (seed) and proceed iteratively
- ▶ Progress schema: $\emptyset, F(\emptyset), F(F(\emptyset)), F^3(\emptyset), F^4(\emptyset), \dots$
- ▶ In our example
 - ▶ $X^0 = \text{seed} = \emptyset$
 - ▶ $X^1 = E^{\text{G}} = \text{direct edges}$
 - ▶ $X^2 = F(X^1) = X^1 \cup \{(x, y) \mid \exists z. E(x, z) \wedge X^1(z, y)\} =$
direct edges or paths of length 2
 - ▶ \dots
 - ▶ $R^{\text{G}'} = \bigcup_{i \in \mathbb{N}} X^i$
- ▶ The fixpoint here is the least fixpoint.
- ▶ **Nota bene**
 - ▶ A fixpoint may not exist
 - ▶ There may be many fixpoints
 - ▶ There may not be a least fixpoint. (Exercise?)

Constructing Least fixpoints

- ▶ Start with extension \emptyset (seed) and proceed iteratively
- ▶ Progress schema: $\emptyset, F(\emptyset), F(F(\emptyset)), F^3(\emptyset), F^4(\emptyset), \dots$
- ▶ In our example
 - ▶ $X^0 = \text{seed} = \emptyset$
 - ▶ $X^1 = E^{\text{G}} = \text{direct edges}$
 - ▶ $X^2 = F(X^1) = X^1 \cup \{(x, y) \mid \exists z. E(x, z) \wedge X^1(z, y)\} =$
direct edges or paths of length 2
 - ▶ \dots
 - ▶ $R^{\text{G}'} = \bigcup_{i \in \mathbb{N}} X^i$
- ▶ The fixpoint here is the least fixpoint.
- ▶ **Nota bene**
 - ▶ A fixpoint may not exist
 - ▶ There may be many fixpoints
 - ▶ There may not be a least fixpoint. (Exercise?)

Fixpoint Construction Graphically

- ▶ fixpoint for $F(x) = \cos(x)$.
- ▶ Attractor

"Cosine fixpoint". Licensed under CC BY-SA 3.0 via Wikimedia Commons - https://commons.wikimedia.org/wiki/File:Cosine_fixed_point.svg#/media/File:Cosine_fixed_point.svg

[//commons.wikimedia.org/wiki/File:Cosine_fixed_point.svg#/media/File:Cosine_fixed_point.svg](https://commons.wikimedia.org/wiki/File:Cosine_fixed_point.svg#/media/File:Cosine_fixed_point.svg)

Recursive Humor

- ▶ Wiki entry **Recursive humor**.
It is not unusual for such books to include a joke entry in their glossary along the lines of: Recursion, see Recursion.[6]

[...] An alternative form is the following, from Andrew Plotkin: "If you already know what recursion is, just remember the answer. Otherwise, find someone who is standing closer to Douglas Hofstadter than you are; then ask him or her what recursion is."

Lit: D. Hofstadter. *Gödel, Escher, Bach: An Eternal Golden Braid*. Vintage Books, 1979.

- ▶ Blog *Recursively Recursive*
<https://recursivelyrecursive.wordpress.com/category/recursive-humour/page/2/>

Datalog

- ▶ The illustrations above were motivated by **Datalog** rule notation
- ▶ Developed around 1980s
- ▶ Renaissance (not only as proof tool but) as industrially applied tool
- ▶ Logic programming characterization: Prolog without function terms (and without other non-declarative stuff such as cuts)
- ▶ EXPTIME-complete in combined complexity; PTIME-complete data complexity
- ▶ Simple evaluation strategy for positive fragment (no negation)
- ▶ Negation calls for hierarchical evaluation (stratification)
- ▶ Different fragments; optimizations ...

Datalog

- ▶ **General Logic Programm:** Finite set of rules of the form

$$\underbrace{\alpha}_{\text{head}} \leftarrow \underbrace{\beta_1, \dots, \beta_n}_{\text{body}}$$

- ▶ α atomic formula; β_i are literals
 - ▶ Free variables \forall quantified; comma read as \wedge
 - ▶ **Intensional relation:** Relation symbol occurring in some head
 - ▶ **Extensional relation:** occurring only in body
-
- ▶ **Datalog program** = logic program with
 - ▶ no function symbols
 - ▶ no intensional relation negated in body
 - ▶ Sometimes additionally **safety constraints:**
 - ▶ all free variables in head also in body
 - ▶ all variables in negated atoms (or arithmetical expressions such as identity) also in non-negated atom in body
 - ▶ Semantics for datalog programs: by step-operator used in parallel for intensional relations

Datalog example: ancestors of Mary

$ans(x) \leftarrow ancestor(x, mary)$
 $ancestor(x, y) \leftarrow parentOf(x, y)$
 $ancestor(x, y) \leftarrow parentOf(x, z), ancestor(z, y)$

SQL 3 Recursion example

```
%Find Mary's ancestors from ParentOf(parent,child)
WITH RECURSIVE Ancestor(anc,desc) AS
    ( (SELECT parent as anc, child as desc FROM ParentOf)
      UNION
      (SELECT Ancestor.anc, ParentOf.child as desc
       FROM Ancestor, ParentOf
       WHERE Ancestor.desc = ParentOf.parent) )
SELECT anc FROM Ancestor WHERE desc = "Mary"
```

FOL with Least fixpoints

- ▶ Datalog extends FOL w.r.t. the semantics (subkutane)
- ▶ There are different extensions of FOL with fixpoint operators **available in the syntax**
- ▶ $\exists FO(LFP)$: existential fragment of FOL with least fixpoint operator $[LFP_{\vec{y}, \gamma} \phi]$
 - ▶ Semantics of $[LFP_{\vec{x}, X} \phi] \vec{t}$ in model \mathfrak{A} :
“For X chosen as least fixpoint, \vec{t} fulfills ϕ in \mathfrak{A} ”
 - ▶ Restriction: X has to occur positively (i.e. after an even number of \neg in ϕ)
(Needed to guarantee existence of lfp)

Theorem

Existential fragment of $\exists FO(LFP)$ is equivalent to Datalog.

0-1 law for Datalog

Theorem

Datalog (without negation and ordering) has the 0-1 law.

- ▶ In particular you can not express EVEN
- ▶ (Adding negation allows to express EVEN, which does not fulfill 0-1 law)
- ▶ In fact a successor relation together with min- and max-predicates is sufficient.

$$\text{odd}(x) \leftarrow \text{min}(x)$$

$$\text{odd}(x) \leftarrow S(x, y), \text{even}(y)$$

$$\text{even}(x) \leftarrow S(y, x), \text{odd}(y)$$

$$\text{EVEN} \leftarrow \text{max}(x), \text{even}(x)$$

0-1 law for Datalog

Theorem

Datalog (without negation and ordering) has the 0-1 law.

- ▶ In particular you can not express EVEN
- ▶ (Adding negation allows to express EVEN, which does not fulfill 0-1 law)
- ▶ In fact a successor relation together with min- and max-predicates is sufficient.

$$\text{odd}(x) \leftarrow \text{min}(x)$$

$$\text{odd}(x) \leftarrow S(x, y), \text{even}(y)$$

$$\text{even}(x) \leftarrow S(y, x), \text{odd}(y)$$

$$\text{EVEN} \leftarrow \text{max}(x), \text{even}(x)$$

What we Did not Cover

- ▶ Very many things, in particular ...
- ▶ Descriptive Complexity
- ▶ Algorithmic Model Theory (Infer meta-theorems on algorithmic properties by considering)
- ▶ Proving equivalence of languages (using types)

Descriptive Complexity

- ▶ There is a close relationship between complexity classes and logics (queries expressible in a logic)
- ▶ Hints to astonishing correspondences between prima facie two different worlds
- ▶ The world of representation (what?) and of calculation (how?)
- ▶ Results talk about data complexity (!)
- ▶ Results mainly for ordered structures

Fagin lays the foundations

- ▶ One of the first insights which founded descriptive complexity goes back to Fagin

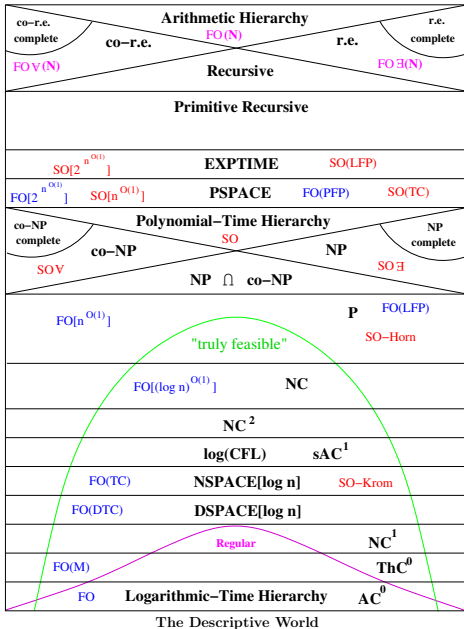

Theorem ($SO\exists$ captures NPTIME)

Existential second order logic ($SO\exists$) captures the class of problems verifiable in polynomial time (NP)

Definition

A logic \mathcal{L} **captures** a complexity class \mathcal{C} iff for all σ with $\langle \in \sigma$ and classes of structures $K \subseteq STRUC(\sigma)$:

$$K \in \mathcal{C} \text{ iff } K \text{ is axiomatizable in } \mathcal{L}$$

The Descriptive World

(Immerman: Descriptive Complexity, ACM SIGACT NEWS, vol. 34, no. 3, 2003, p.5)

Exercise 4 (16 Points)

Exercise 4.1 (6 Points)

Use Hanf locality in order to proof that the following boolean queries are not FOL-definable.

1. graph acyclicity
2. tree

Exercise 4.2 (4 Points)

Show that $EVEN(\sigma)$ can be defined within second-order logic.

Hint: formalize “There is a binary relation which is an equivalence relation having only equivalence classes with exactly two elements” and argue why this shows the axiomatizability.

Exercise 4.3 (2 Points)

Argue why (in particular within the DB community) one imposes safety conditions for Datalog rules.

Exercise 4.4 (4 points)

Give examples of general program rules for which

1. No fixpoint exists at all (Hint: "This sentence is not true")
2. Has two minimal fixpoints (Hint: "The following sentence is false. The previous sentence is true.")
